

Problem 1. Electrostatics and Dielectrics.

A point charge q is located in free space a distance d from a semi-infinite block of dielectric of relative dielectric constant $\kappa = \epsilon / \epsilon_0$.

The electrostatic potential for this system is

$$V(x, y, z) = \frac{q}{4\pi\epsilon_0} \left[\frac{1}{\sqrt{(x+d)^2 + y^2 + z^2}} + \frac{1-\kappa}{1+\kappa} \frac{1}{\sqrt{(x+d)^2 + y^2 + z^2}} \right]$$

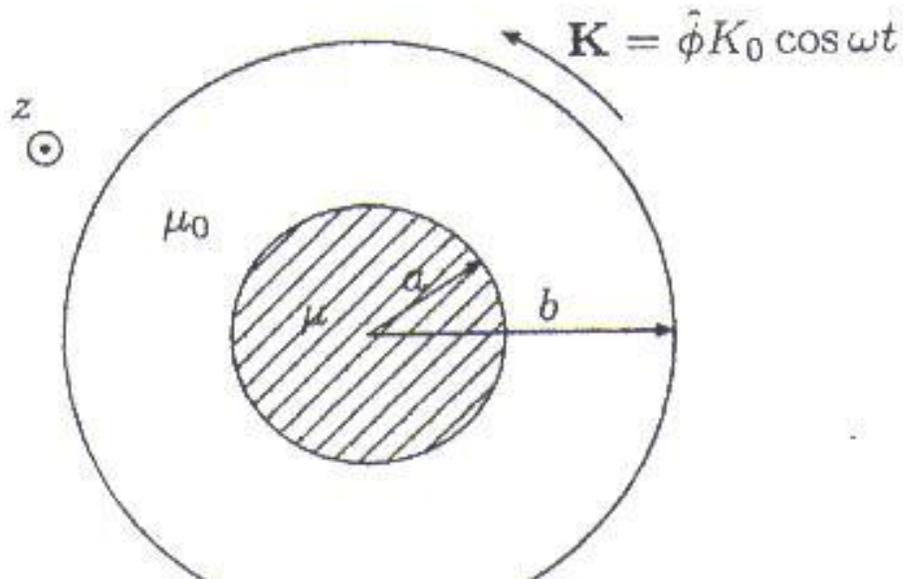

$$= \frac{q}{4\pi\epsilon_0} \frac{2}{1+\kappa} \frac{1}{\sqrt{(x+d)^2 + y^2 + z^2}}$$

10 pts (a) Find the electric field E in the dielectric block region $x > 0$.

10 pts (b) Find the bound surface charge density σ_b [C/m²] at the surface $x = 0$.

10 pts (c) Find the electrostatic force acting on the charge q (both magnitude and direction).

Problem 2. Magnetostatics Faraday's Law

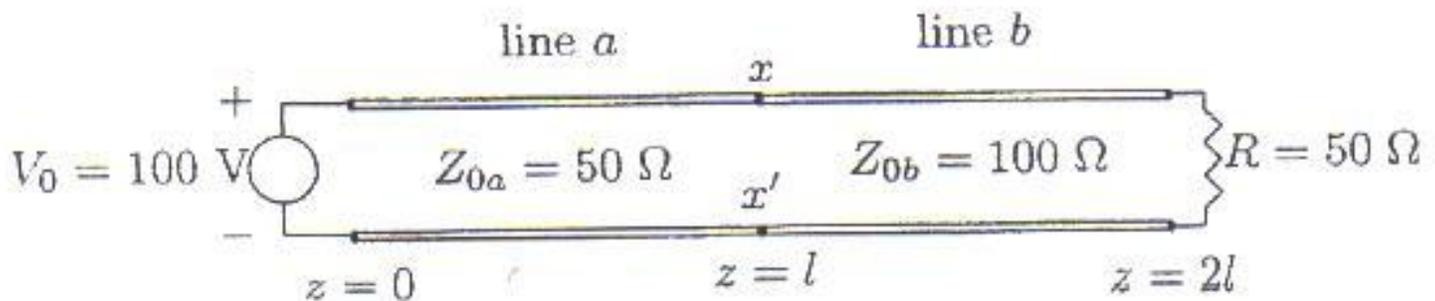

An infinite cylindrical solenoid of radius b whose axis lies along the z -axis is partially filled with a concentric ferrite (nonconducting) rod having a radius $a < b$ and permeability $\mu > \mu_0$. A low frequency surface current $\mathbf{K} = \hat{\phi} K_0 \cos \omega t$ [A/m] flows in the ϕ -direction on the surface of the solenoid at $r = b$.

10 pts (a) Assume that the frequency ω is low enough that the laws of magnetostatics can be used to determine the time-varying magnetic fields, Find the (time-varying) magnetic field \mathbf{H} and magnetic induction \mathbf{B} everywhere within the solenoid ($r < b$).

10 pts (b) Using Faraday's law find the induced (time-varying) electric field $\mathbf{E}(r, t)$ everywhere within the solenoid ($0 < r < b$).

Problem 3. Pulsed and Sinusoidal Transmission Line Excitations.

Two ideal lossless transmission lines, a and b, having lengths $l = 200 \text{ m}$ and propagation velocities $v = 2 \text{ E}8 \text{ m/s}$, are connected together. The system is excited at the left on line a by an ideal dc voltage source $V_0 = 100 \text{ V}$ and terminated at the right on line b by a resistor $R = 50 \text{ ohms}$. Lines a and b have characteristic impedances $Z_{0a} = 50 \text{ ohms}$ and $Z_{0b} = 100 \text{ ohms}$, respectively.

10 pts (a) Assuming that the voltage source V_0 has been connected for a long time ($-\infty < t < 0$), what is the voltage (in volts) and the current (in amperes) at all points along lines a and b? Find (in volts) the forward and backward traveling waves (V_{a+} , V_{a-} and V_{b+} , V_{b-}) on lines a and b at time $t = 0$.

10 pts (b) Now assume that the dc voltage source is replaced by an ideal rf voltage source $V(t) = V_0 \cos \omega t$, where $\omega = \pi/2 \text{ E}6 \text{ rad/s}$. Find the impedance $Z_{xx'}$ (real and imaginary parts in ohms) looking to the right at the junction $x-x'$ joining lines a and b. You may use the Smith chart to do the calculation if you wish.

10 pts (c) For what values of ω will the voltage source of part (b) be matched to its load (no backward wave on line a; i.e., $V_{a-} = 0$)?
